

Preparació per realitzar l'anàlisi de dades

Per realitzar la primer tasca, he buscat els *flags* de la comanda *docker run* per poder modificar la quantitat de peticons i el nivell de concurrència (-n, -c). Seguidament, utilitzant el web server *nginx* configurat amb una concurrència d'una CPU i amb un nombre considerable de peticions, a l'executar l'*Apache ab* he obtingut les dades següents:

```
guillem@guillem-SATELLITE-P70-B:~/proba/docker-ab$
guillem@guillem-SATELLITE-P70-B:~/proba/docker-ab$ docker run --rm jordi/ab -n 400 -c 1 https://www.docker.com/

guillem@guillem-SATELLITE-P70-B:~/proba/docker-ab$
```

Primerament cal destacar les dades obtingudes referents al nombre de CPUs utilitzats. Aquest nombre el podem veure al paràmetre "Concurrency Level". El següent paràmetre rellevant és aquell que ens ajuda a veure el TPS que hem tingut en les nostres peticions. Aquest, el podem veure en el paràmetre "Request per second".

Un cop adquirits aquests coneixements, vaig procedir a realitzar proves variant el nombre de CPUs utilitzats (augmentant així la concurrència) per intentar trobar la configuració òptima per obtenir el millor rendiment de la relació ús de la CPU-Transaccions Per Segon. Abans de realitzar proves, vaig fer la premissa següent:

"El valor del TPS augmentarà a mesura que augmentem la concurrència i l'ús de CPU augmentarà poc a poc fins que arribi el punt que el TPS ja no pujarà o l'augment d'aquest no pujarà el suficient per compensar l'augment de l'ús de la CPU. D'aquesta manera, trobant el punt d'inflexió, obtindrem la configuració òptima".

A més a més, vaig comprovar el nombre de CPUs del meu ordinador. Aquest és de 4 i, per tant, el meu ordinador té 8 threads.

```
processor      : 6
vendor_id     : GenuineIntel
cpu family    : 6
model         : 60
model name    : Intel(R) Core(TM) i7-4720HQ CPU @ 2.60GHz
stepping      : 3
microcode     : 0x27
cpu MHz       : 1401.460
cache size    : 6144 KB
physical id   : 0
siblings      : 8
core id       : 3
cpu cores     : 4
```

Realització de Proves

A continuació, adjunto les proves realitzades més rellevants:

4000	4000	93,7 req/seg	55,8%	268

Gràfic de l'evolució de l'ús de CPU en relació al nivell de concurrència

Gràfic de l'evolució del TPS en relació al nivell de concurrència

Conclusions

Amb l'ajuda d'aquesta taula i gràfics dels resultats obtinguts veig que la premissa inicial no anava massa desencaminada. Es pot observar que el valor del TPS i de l'ús de la CPU augmenten de diferent mesura segons la concurrència que apliquem i veiem dos punts de tall, un en el 4 i l'altre en els nombres enormes de threads.

Analitzant detingudament les dades, podem extreure les següents conclusions:

- La configuració **òptima** està en la **concurrència = 4** (4 *threads*), ja que és el punt on el percentatge de CPU que augmenta es molt inferior a la quantitat de TPS que obtenim. A partir dels 5 *threads*, la quantitat de TPS i de CPU augmenta en una relació directament proporcional amb l'augment del nombre de *threads* que utilitzem.
- Quan posem un **nombre molt considerable** de *threads*, és quan comencen a aparèixer els **errors**. Això podria ser degut a que com l'ordinador només té 4 CPUs. Suposant que les peticions que tenen un **temps límit** per executar-se, hi haurà threads, dels que hem assignat a una petició, que trigaran molt a poder executar-se, fet el qual podria ser degut a la disponibilitat de la CPU amb tants *threads*, els quals acaben sense haver pogut dur a terme la seva feina assignada.
- Quan tenim un nombre enorme de *threads*, a part d'aparèixer errors, l'ús de la CPU es dispara però baixa molt considerablement el TPS.
